

Rotor Analysis

Joe Spencer

October 17, 2022

Methods

A rotor's performance can be computed using [Blade Element Moment Theory](#). This computation makes it possible to estimate how well a rotor will perform under various conditions without having to produce and test many prototypes. The Blade Element Momentum Theory calculations for this lab were conducted using BYU FLOW Lab's [CCBlade.jl](#) header file. Used together with other julia header files, including [Xfoil.jl](#), A rotor's [Power](#), [Thrust](#), and [Torque](#) distributions could be calculated, as well as its [Efficiency](#).

Some non-dimensional numbers in rotor analysis are the coefficients of power, thrust, and torque. Each of these coefficients relates a useful quantity to other known quantities including the air density, the blade diameter, and rotor's rotational velocity. Figure 1 shows that changing the blade diameter does not change any of these coefficients. This same result would happen if air density or blade diameter were changed. Although the propellor would move at a different velocity and experience different forces, its coefficients would be unchanged.

Other non-dimensional constants in airfoil analysis include the [Advance Ratio](#) and [Tip Speed Ratio](#), the [Axial](#) and [Tangential](#) Induction factors, the [Efficiency](#), and the [Rotor Solidity](#). Some of these terms are closely related. For example, the tip speed ratio is simply π divided by the advance ratio, and the power coefficient is the torque coefficient multiplied by a factor of 2π . Each number provides a benchmark reference that can relate similar airfoils under different conditions.

Since it combines two theories to obtain the power, thrust, torque, and efficiency of an airfoil, CCBlade uses a system of equations to find them. The following equations are solved in this system to find the [Axial Induction Factor](#), a , [Tangential Induction Factor](#), and [Angle of Rotation](#), ϕ . A detailed description of other variables in this system of equations can be found in the [Glossary](#).

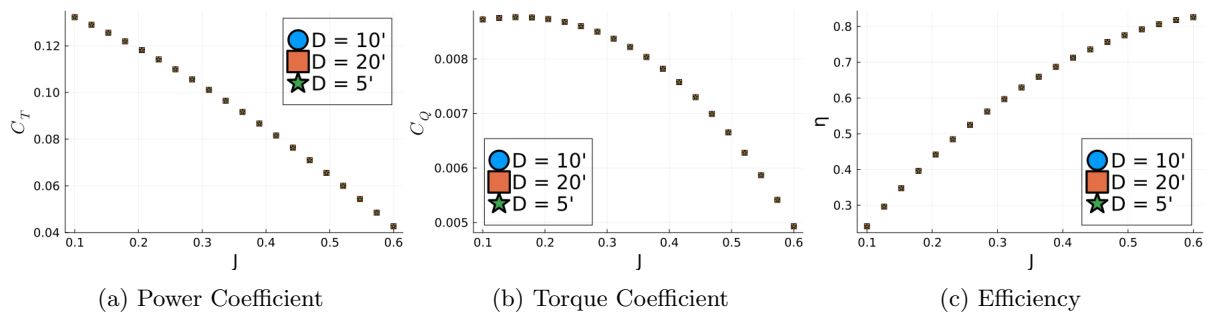

Figure 1: Comparison Between Similar Rotors of Varying Diameter

Adjusting a propellor's radius does not change the power, thrust, or torque coefficients as long as its geometry remains the same.

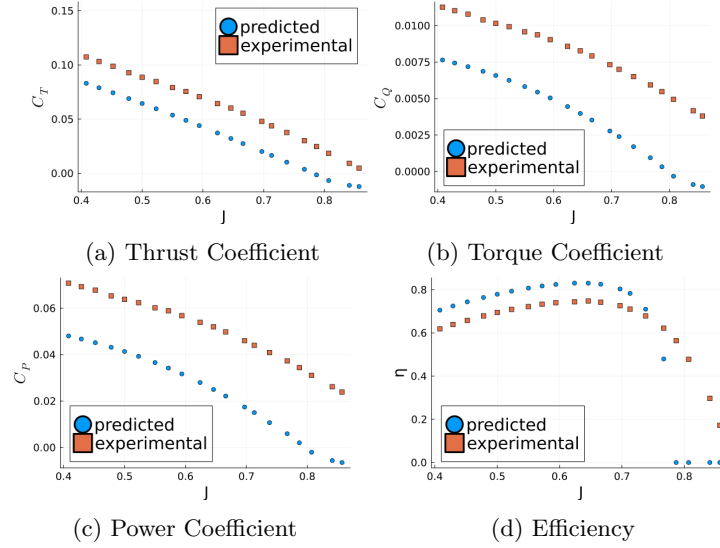

Figure 2: Testing BEM Output Against Experimental Data.

Although there are some differences, Blade Element Momentum code provides a good estimate of the constants experienced by a rotor.

$$\begin{aligned}
 \frac{1}{2}W^2 N c C_y &= 4\pi U_\infty (1 - a) \times \Omega a' r^2 \\
 \frac{1}{2}\rho W^2 N c C_x &= 4\pi \rho [(a' \Omega r)^2 + \Omega_\infty^2 a(1 - a)]r \\
 \sin \phi &= \frac{U_\infty}{W} (1 - a)
 \end{aligned} \tag{1}$$

Once these equations are solved, Axial Induction Factor and Tangential Induction Factor provide the ratios of increase and reduction in fluid flow velocity in the normal and tangential directions to the rotor. The angle of rotation provides the angle that the airfoil should form with the free stream velocity to achieve this result. The system of three equations shown is possible because it combines equations from both theories.

After this system of equations is solved, the solutions for a , a' , and ϕ are used to find C_P , C_T , C_Q and η for an airfoil. The user can compare these values at different angles of attack to determine which advance ratio is best for an application. Different [Twist Distributions](#), [Hub-to-tip Ratios](#), [Chord Distributions](#), and [Propellor Types](#) can also be investigated to compare their performances.

Results and Discussion

This research led to a few discoveries that will be useful to optimize a rotor in the next assignment. These discoveries refined the size, shape, velocity, and blade quantity of rotors and gave insights into what results from changing each variable quantity.

1. Comparison to Experimental Data

I first compared experimental rotor data with my own CCBlade computations. CCBlade.jl has a [github Repository](#) containing some experimental data, which I used to test the functions I created. Figure 2 shows that the code found solutions close to experimental data. This is useful, because obtaining airfoil performance data in a physical experiment is very difficult. There are also many

Figure 3: Comparison Between Rotors of Different Length and Pitch

Increasing a rotor's length appears to slightly increase its coefficients of thrust and torque. Decreasing a rotor's pitch dramatically decreases its efficiency at higher advance ratios.

Figure 4: Comparison Between Rotors of Different Chord Magnitude

In these plots, a rotor is thickened or thinned by 20 percent.

factors which could potentially invalidate these experimental results that are hard to control.

A loop calculated the error by finding the square root of the average of the squared residuals. The calculated errors were 28.8 percent for efficiency, 37.7 percent for the thrust coefficient, and 51.4 percent for both the thrust and torque coefficients. These were much larger than the errors calculated in the provided data, which were 9.1 percent, 7.8 percent, and 5.4 percent. This may have been do to different methods of data collection or measurement.

The graphs of the torque coefficient and the pressure coefficient have the same shape. They are related by a 2π factor. Future plots will only display the torque coefficient because of this.

2. Radius

As shown in figure 1, the radius factor is not included in any of the non-dimensional numbers investigated in this lab. If the size of the rotor is scaled then no effect occurs. Increasing a rotor's diameter while keeping other factors the same can have an effect, though. Figure 3 Shows a NACA 10x7 and 11x7 rotor compared to each other. The longer NACA 11x7 propellor exhibits greater coefficients of thrust and torque with a similar efficiency.

3. Chord Distribution

Figure 4 shows that increasing or decreasing a rotor's chord distribution has insignificant impact on its efficiency. Changing the magnitude of the chord has an enormous impact on the torque and power coefficients, though. Thickening a rotor will dramatically increase the thrust and torque coefficients. So, in general to increase the thrust a rotor generates, it should be thickened.

Figure 5: Comparison Between Twist Angles

These rotors are identical besides the angle with which they were uniformly twisted.

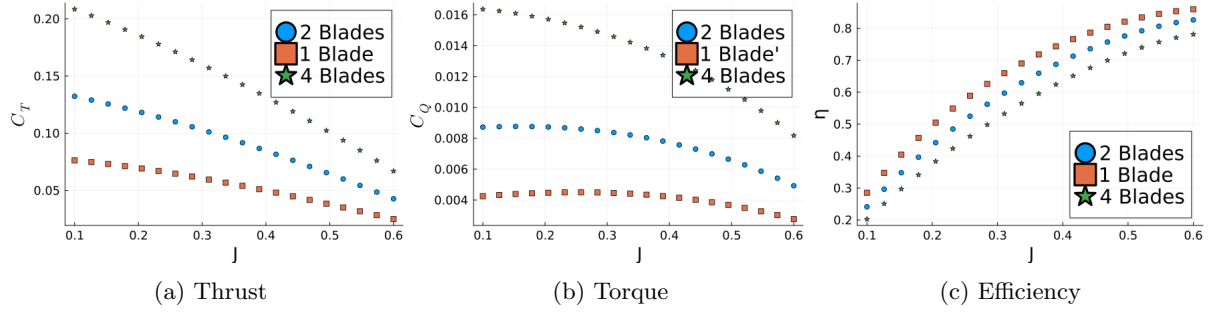

Figure 6: Comparison Between Twist Angles

Although thrust and torque increase with each added rotor blade, efficiency decreases.

4, *Twist Distribution*

The amount a rotor is twisted can be modified so it redirects airflow and thrust differently to produces different effects. The three rotors in figure 5 are twisted different amounts, and their thrust, torque, and efficiencies all varied significantly. The rotor with a -5° twist had the lowest thrust, torque, and efficiency. Its efficiency plot is at zero because the force generated by air flowing past rotor acts against its motion.

5, *Blade Count*

Increasing the number of blades in a rotor appears to increase both the thrust and torque it generates. While the thrust and torque increase, though, the efficiency decreases as rotor blades begin to decrease airflow instead of generating more thrust.

1 Glossary

- Advance Ratio, J - A rotor's Advance Ratio is a non-dimensional term. It describes the ratio how quickly a rotor is moving relative to the fluid flowing past it. A high advance ratio signifies that either the fluid is moving quickly or the rotor is moving slowly. It is described by the following equation, in which V_a is the free stream fluid velocity, n is the rotational velocity, and D is the rotor diameter.

$$J = \frac{V_a}{nD} \quad (2)$$

- Angle of Rotation, ϕ - The Angle of Rotation, sometimes denoted by the Greek letter ϕ , is the angle between the freest stream velocity and the velocity of the airfoil as it rotates. It is used in [Blade Element Momentum Theory](#) calculations.
- Axial Induction Factor, a - The Axial Induction Factor is the ratio of the reduction in air velocity at an airfoil to its free stream velocity.
- Blade Element Momentum Theory - The theory used to calculate local forces on a propellor or wind turbine blade. It employs both [Blade Element Theory](#) and [Momentum Theory](#). These equations are used to recursively find the [Axial Induction Factor](#), a , [Tangential Induction Factor](#), and [Angle of Rotation](#), ϕ

$$\begin{aligned} \frac{1}{2}W^2NcC_y &= 4\pi U_\infty(1-a) \times \Omega a' r^2 \\ \frac{1}{2}\rho W^2NcC_x &= 4\pi\rho[(a'\Omega r)^2 + \Omega_\infty^2 a(1-a)]r \\ \sin\phi &= \frac{U_\infty}{W}(1-a) \end{aligned} \quad (3)$$

In these equations, a , a' , and ϕ are the previously mentioned axial and tangential induction factors and angle of rotation. The airfoil's apparent speed is represented by the letter W , N is the number of propellers, ρ is the fluid density, c is the chord length, C_x and C_y are obtained by the equation below, U_∞ is the fluid free velocity, Ω is the blade's angular speed, and r is the radius to the tip of the blade.

$$\begin{aligned} C_x &= c_l \cos\phi + c_d \sin\phi \\ C_y &= c_l \sin\phi + c_d \cos\phi \end{aligned} \quad (4)$$

- Blade Element Theory - Blade Element Theory calculates the forces on a turbine blade by dividing it into finite pieces and summing the forces on all of these pieces. This theory determines the induced velocity and efficiency of a point along a blade using these equations:

$$\begin{aligned} v_i &= \sqrt{\frac{T}{A} \frac{1}{2\rho}} \\ \eta &= \frac{\tan\phi}{\tan(\phi + \gamma)} \end{aligned} \quad (5)$$

In these equations, v_i is the uniform induced velocity across the disk, T the thrust it experiences, A is its area, ρ is the air density, ϕ is the angle to the airfoil's plane of rotation as it moves forward, and γ is the difference between ϕ and β , what the airfoil's actual angle of rotation would be if it were stationary.

- Chord Distribution - The Chord Length Distribution shows the length of a rotor's chord at different angular positions around itself. An airfoil with a constant angle of attack α as it generates lift has an elliptic chord distribution.

- Coefficient of Power, C_P - A propellor's Coefficient of Power signifies how efficient a wind turbine is. It is the ratio of the power generated by a wind turbine to the total power of the wind flowing through it. The power generated or absorbed by an airfoil can be described by the following equation, where P is power, C_P is the coefficient of power, ρ is fluid density, n is the velocity in revolutions per second, and D is the propellor diameter. The Power Coefficient and the [Torque Coefficient](#) are proportional to each other by a factor of 2π .

$$\begin{aligned} P &= \rho n^3 D^5 C_P \\ C_P &= 2\pi C_Q \end{aligned} \quad (6)$$

- Coefficient of Thrust, C_T - A rotor's Thrust Coefficient determines how much thrust in the forward direction an airfoil experiences. Thrust force is directly opposite drag. Please note the similarities and differences between the thrust equation and the [power equation](#).

$$T = \rho n^2 D^4 C_T \quad (7)$$

- Coefficient of Torque, C_Q - A rotor's Torque Coefficient defines how much torque it will experience. A propellor's torque is given by the following equation, in which Q represents torque, ρ is the fluid density, n is the velocity in revolutions per second, D is the diameter, and C_Q is the coefficient of torque. The Torque Coefficient and the [Power Coefficient](#) are proportional to each other by a factor of 2π .

$$\begin{aligned} Q &= \rho n^2 D^5 C_Q \\ C_Q &= \frac{C_P}{2\pi} \end{aligned} \quad (8)$$

- Efficiency, η - The Efficiency of a rotor can be described by the following equation, in which J is the rotor's [Advance Ratio](#), C_T is its [thrust coefficient](#), and C_P its [power coefficient](#):

$$\eta = J \frac{C_T}{C_P} \quad (9)$$

- Hub-to-Tip Ratio - A rotor's Hub-to-Tip Ratio divides the distance along the blade that is actually exposed wind by the entire length of the blade. This needs to be taken into account when calculating constants like the airfoil's [tip speed ratio](#).
- Momentum Theory - Momentum Theory defines the power required to produce sufficient thrust to maintain momentum in a blade by the following equation, where T is thrust, ρ is density, A is disc area, and P is power:

$$P = \sqrt{\frac{T^3}{2\rho A}} \quad (10)$$

- Propellor Identification - A Propellor is identified by 2 numbers, which represent its diameter and its pitch, both in inches. For example, an APC 10x7 propellor is made by Advanced Precision Composites. It has a 10-inch diameter and a 7-inch pitch per revolution.
- Rotor Solidity, σ - Rotor Solidity describes the ratio of a turbine's chord length, c , to its spacing, s . This is found by the following equation, in which n_b is the number of blades, r_h is the hub radius, and r_t is the tip radius.

$$\sigma = \frac{c}{s} = \frac{cn_b}{2\pi \sqrt{\frac{r_h^2 + r_t^2}{2}}} \quad (11)$$

- Tangential Induction Factor, a' - The Tangential Induction Factor is the ratio of the increase in air velocity tangential to the airfoil to its free stream velocity.

- Tip Speed Ratio, λ - A wind turbine's Tip Speed Ratio is the inverse of its [Advance Ratio, \$J\$](#) . It represents the ratio of the speed of the tip of a turbine blade, or ωR , to the wind speed, v .

$$\lambda = \frac{\omega R}{v} = \frac{\pi}{J} \quad (12)$$

- Twist Distribution - Twist distribution along a wing redirects where air flows past it. This causes changes in both the magnitude and location lift and drag forces it experienced as air flows past it.
